In today's digital world, running an online business means **more than just delivering great products or services**, it also means **defending** your website from a growing wave of **cyber threats**.

Cybersecurity can be a bit **tedious** and **complicated** for non-professionals, so using **tools that simplify the process of defending** against threat actors can make the difference between a **secure website** and a **costly GDPR fine + bad PR**.

1. BreachCollection

BreachCollection is a website that allows you to **check for leaked data** about your business, and **prevent Credential Stuffing**, an upcoming threat for web applications.

Its dashboard has a very **simple** interface: **It works like a search engine**, like Google, but for data breaches! You can do several types of queries:

- **Email Query** (search for leaks associated with an email address)
- **Domain Query** (credentials that log you in a domain)
- **Email Domain** (leaks for all of the email addresses ending with a domain ex “@example.com”)
- **Personal Information** (phone numbers, addresses, postal codes, Names, Date of Birth, etc...)

With this tool you can find **all leaked credentials for your website**. This is especially useful if you provide a **service/content behind a paywall**, because **malicious users can leverage leaked accounts** to gain unauthorized access to that **service/content for free**.

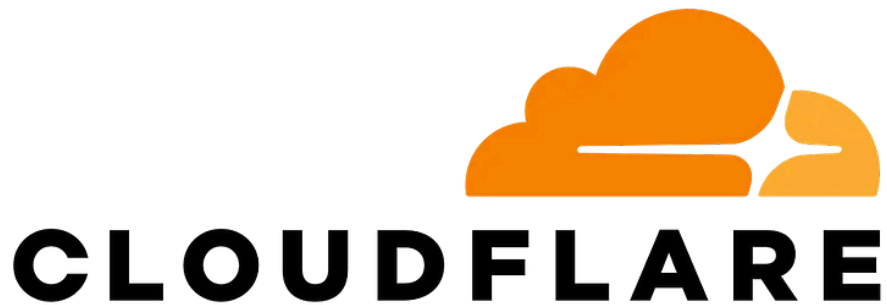

This service's Database is continuously being updated, ensuring you are **always protected from threat actors**.

Breachcollection **offers an API**, which lets you submit a users' password (MD5 hashed, to ensure privacy) and it **returns whether it has been found in a Data Breach or not**. That way, you can go the extra mile when ensuring your **user's passwords are safe**.

You can very easily integrate this feature with signups on your website, so **when a user signs up, it checks whether their password is safe or not**.

2. Cloudflare

Cloudflare offers a range of services for your website, including a firewall, bot protection, analytics, caching, and many more.

After you tie your website to Cloudflare, most of these functions can be activated with a single click, making it extremely easy to use this platform to protect your website from most web attacks.

Cloudflare does also protect you against DDoS and Brute Force attacks, which are very common attacks that may result in downtime or unwanted data extraction.

Cloudflare's free tier offers a wide range of features, and can be a valuable tool for improving your website's security and performance.

3. Mozilla Observatory

On [Mozilla Observatory](#), you can run a free quick scan on your website. It helps you check if you comply with a few web security best practices.

The scan takes **about 10 seconds**, and it is a good way to get feedback about your web security.

HTTP Observatory

Launched in 2016, the HTTP Observatory enhances web security by analyzing compliance with best security practices. It has provided insights to over 6.9 million websites through 47 million scans.

You will receive a grade, from F to A+, along with tailored recommendations on how to fix existing issues.

Conclusion

All of these tools offer amazing functionalities and combined can make a significant difference on your website's security.

The use of these tools combined with a **security-first mindset**, can go a long way in protecting user data, building trust, and preventing common web attacks.
